Scientific Benchmark Report

BoolMinGeo vs SymPy (5-8 Variables)

3D geometric approach vs symbolic simplification

Experiment Date: 2026-01-09

Random Seed: 42

Total Test Cases: 840

Statistical Significance Level: α = 0.05

A Rigorous Statistical Analysis with Reproducibility Controls

EXPERIMENTAL SETUP

SYSTEM CONFIGURATION

```
Python Version:   3.12.10
Platform:         Windows-11-10.0.26200-SP0
Processor:        Intel64 Family 6 Model 142 Stepping 12, GenuineIntel
```

LIBRARY VERSIONS

```
SymPy:            1.14.0
NumPy:            2.3.4
SciPy:            1.16.3
```

EXPERIMENTAL PARAMETERS

```
Random Seed:                 42
Tests per Distribution:      20
Tests per Configuration:     105
Timing Warm-up Runs:         1
Timing Repetitions:          3
Significance Level (α):      0.05
```

TEST CONFIGURATIONS

- 5-variable K-maps (32 minterms)
- 6-variable K-maps (64 minterms)
- 7-variable K-maps (128 minterms)
- 8-variable K-maps (256 minterms)

METHODOLOGY

1. Random and pattern-based test cases generated
2. Each algorithm executed with 1 warm-up runs
3. Best of 3 timed repetitions recorded
4. Logical equivalence verified using SymPy
5. Statistical significance tested using paired t-tests
6. Non-parametric Wilcoxon tests used as robustness check
7. Effect sizes computed using Cohen's d

TRIVIAL CONSTANT CASES

Constant functions (all-zeros→False, all-ones→True, all-dc) are already maximally simplified. Both algorithms correctly identify these degenerate cases. They are excluded from literal-count statistics but included in performance and equivalence analysis.

REPRODUCIBILITY

To reproduce this experiment:

1. Set random seed: random.seed(42)
2. Run with identical system configuration
3. Use same library versions as documented above

```
===========================================================================

STATISTICAL INFERENCE REPORT

===========================================================================

□□  TRIVIAL CONSTANT CASES DETECTED: 3/105 (2.9%)
   These are degenerate constant functions (all-zeros→False, all-ones→True,
   all-dc) that are already maximally simplified. Both algorithms correctly
   identified them. Included in performance/equivalence analysis but excluded
   from literal-count statistics.

1. EXECUTION TIME ANALYSIS

---------------------------------------------------------------------------
Mean SymPy Time:        0.009272 s
Mean BoolMinGeo Time:   0.006195 s
Mean Difference:        -0.003076 s
Std. Dev. (Δ):          0.007235 s
95% CI:                 [-0.004476, -0.001676]

Paired t-test:          t = -4.3566, p = 0.000031
Wilcoxon test:          W = 1279.0, p = 0.000002
Effect Size (d):        -0.4252 (small)

✓ SIGNIFICANT: Time difference is statistically significant (p < 0.05)
  → BoolMinGeo is significantly faster than SymPy

2. SIMPLIFICATION QUALITY ANALYSIS

---------------------------------------------------------------------------
Analysis based on 102 non-constant functions:
(3 constant function(s) excluded from this analysis)

Mean SymPy Literals:    20.55
Mean KMap Literals:     12.62
Mean Difference:        -7.93
Std. Dev. (Δ):          6.40
95% CI:                 [-9.19, -6.67]

Paired t-test:          t = -12.5198, p = 0.000000
Wilcoxon test:          W = 10.5, p = 0.000000
Effect Size (d):        -1.2396 (large)

✓ SIGNIFICANT: Literal count difference is statistically significant (p < 0.05)
  → BoolMinGeo produces more minimal expressions

3. MEMORY USAGE ANALYSIS (SPACE COMPLEXITY)

---------------------------------------------------------------------------
Mean SymPy Memory:      0.01 MB
Mean KMap Memory:       0.02 MB
Mean Difference:        +0.01 MB
Std. Dev. (Δ):          0.01 MB
95% CI:                 [0.01, 0.01]

Paired t-test:          t = 16.6603, p = 0.000000
Wilcoxon test:          W = 92.0, p = 0.000000
Effect Size (d):        1.6259 (large)

Memory Efficiency:      0.49×
  → SymPy uses 48.6% of BoolMinGeo's memory

✓ SIGNIFICANT: Memory difference is statistically significant (p < 0.05)
  → SymPy uses significantly less memory

===========================================================================

STATISTICAL INFERENCE REPORT

===========================================================================

□□  TRIVIAL CONSTANT CASES DETECTED: 3/105 (2.9%)
   These are degenerate constant functions (all-zeros→False, all-ones→True,
   all-dc) that are already maximally simplified. Both algorithms correctly
   identified them. Included in performance/equivalence analysis but excluded
   from literal-count statistics.

1. EXECUTION TIME ANALYSIS

---------------------------------------------------------------------------
Mean SymPy Time:        0.239783 s
Mean BoolMinGeo Time:   0.021385 s
Mean Difference:        -0.218398 s
Std. Dev. (Δ):          0.271809 s
95% CI:                 [-0.271000, -0.165797]

Paired t-test:          t = -8.2334, p = 0.000000
Wilcoxon test:          W = 32.0, p = 0.000000
Effect Size (d):        -0.8035 (large)

✓ SIGNIFICANT: Time difference is statistically significant (p < 0.05)
  → BoolMinGeo is significantly faster than SymPy

2. SIMPLIFICATION QUALITY ANALYSIS

---------------------------------------------------------------------------
Analysis based on 102 non-constant functions:
(3 constant function(s) excluded from this analysis)

Mean SymPy Literals:    103.50
Mean KMap Literals:     17.97
Mean Difference:        -85.53
Std. Dev. (Δ):          35.35
95% CI:                 [-92.47, -78.59]

Paired t-test:          t = -24.4341, p = 0.000000
Wilcoxon test:          W = 9.5, p = 0.000000
Effect Size (d):        -2.4193 (large)

✓ SIGNIFICANT: Literal count difference is statistically significant (p < 0.05)
  → BoolMinGeo produces more minimal expressions

3. MEMORY USAGE ANALYSIS (SPACE COMPLEXITY)

---------------------------------------------------------------------------
Mean SymPy Memory:      0.08 MB
Mean KMap Memory:       0.03 MB
Mean Difference:        -0.05 MB
Std. Dev. (Δ):          0.05 MB
95% CI:                 [-0.05, -0.04]

Paired t-test:          t = -9.5535, p = 0.000000
Wilcoxon test:          W = 360.0, p = 0.000000
Effect Size (d):        -0.9323 (large)

Memory Efficiency:      2.51×
  → BoolMinGeo uses 39.8% of SymPy's memory

✓ SIGNIFICANT: Memory difference is statistically significant (p < 0.05)
  → BoolMinGeo uses significantly less memory

SCALABILITY ANALYSIS

```
COMPLEXITY MODELS
======================================================================
SymPy Exponential Model:
  T ≈ 5.33e-08 × 8.998^n

BoolMinGeo Exponential Model:
  T ≈ 2.25e-04 × 1.930^n

Growth Rate Analysis:
  SymPy base growth factor:        8.998
  BoolMinGeo base growth factor: 1.930
  Ratio (SymPy/KMap):              4.66×

  → SymPy's execution time grows 4.66× faster per
    additional variable compared to BoolMinGeo

MODEL VALIDATION
======================================================================
Prediction accuracy (measured vs model):
  5-var: SymPy 65.6% error, KMap 4.7% error
  6-var: SymPy 21.3% error, KMap 1.9% error
  7-var: SymPy 0.8% error, KMap 0.1% error
  8-var: SymPy 0.0% error, KMap 0.1% error

Model fit quality: Acceptable

OBSERVED PERFORMANCE
======================================================================
Measured Speedup Factors (BoolMinGeo advantage):

  5 variables:  1.4× faster
  6 variables:  3.1× faster
  7 variables:  11.3× faster
  8 variables:  52.8× faster

Trend: Speedup increases exponentially with problem size

EXTRAPOLATED PERFORMANCE
======================================================================
Projected 9-variable minimization:
  SymPy expected time:         20.623 s
  BoolMinGeo expected time:  0.084 s
  Projected speedup:           246.4×

Projected 10-variable minimization:
  SymPy expected time:         185.565 s
  BoolMinGeo expected time:  0.162 s
  Projected speedup:           1149.0×

PRACTICAL IMPLICATIONS
======================================================================
For 5-6 variables:
  • Both algorithms complete in <10ms
  • Choice can be based on convenience/API preference
  • Performance difference negligible for most applications

For 7 variables:
  • BoolMinGeo shows clear advantage (~15× faster)
  • SymPy: ~40ms, BoolMinGeo: ~3ms
  • Recommended: BoolMinGeo for time-critical applications

For 8 variables:
  • BoolMinGeo demonstrates dramatic advantage (~98× faster)
  • SymPy: ~566ms, BoolMinGeo: ~6ms
  • Highly recommended: BoolMinGeo for any real-time use

For 9+ variables:
  • SymPy becomes impractical (>5s projected for 10-var)
  • BoolMinGeo remains efficient (<50ms projected for 10-var)
  • Essential: Use BoolMinGeo for large-variable problems

ALGORITHMIC COMPLEXITY INSIGHTS
======================================================================
The exponential scaling difference suggests:

1. SymPy's approach has higher algorithmic complexity for
   large variable counts, likely due to more extensive symbolic
   manipulation and optimization attempts.

2. BoolMinGeo's hierarchical K-map decomposition maintains
   better scalability by exploiting the structural properties
   of Boolean functions.

3. For embedded systems or real-time synthesis applications
   requiring 7+ variables, BoolMinGeo offers significant
   practical advantages.

VALIDITY CONSIDERATIONS
======================================================================
• Extrapolations based on exponential model fitting
• Actual performance may vary with function complexity
• Timing includes Python overhead (not pure algorithm cost)
• Models validated on 4 data points (5-8 variables)
```

Mean SymPy Memory:        0.1076 MB
Mean KMap Memory:         0.0301 MB
Mean Memory Difference:   -0.0774 MB
95% CI:                   [-0.0874, -0.0675]
Statistical Significance: YES (p = 0.000000)
Effect Size:              -0.5266 (medium)

KEY FINDINGS
======================================================================

1. BoolMinGeo demonstrates statistically significant performance
   advantage over SymPy's minimization approach.

2. BoolMinGeo produces statistically more minimal Boolean
   expressions (fewer literals) compared to SymPy.

3. BoolMinGeo demonstrates superior memory efficiency,
   using 28.0% of SymPy's memory consumption.

4. Effect sizes indicate small practical
   significance for performance, large practical
   significance for simplification quality, and medium practical
   significance for memory usage.

5. SCALABILITY ANALYSIS reveals exponential performance divergence:
   • 5-var: 1.4× speedup  |  6-var: 3.1× speedup
   • 7-var: 11.3× speedup  |  8-var: 52.8× speedup
   → BoolMinGeo's advantage increases dramatically with problem size
   → See 'Scalability Analysis' section for extrapolations to 9-16 vars

6. All 840 test cases maintained logical correctness,
   with 840 passing equivalence verification.
   Constant cases were 24 (i.e., trivial degenerate cases
   correctly identified by both algorithms).

THREATS TO VALIDITY
======================================================================
• Random test case generation may not reflect real-world distributions
• Timing includes Python overhead (not pure algorithm performance)
• SymPy uses different minimization strategies (not pure K-map based)

REPRODUCIBILITY
======================================================================
This experiment used random seed 42 and can be fully reproduced
using the documented experimental setup and library versions.

RECOMMENDATIONS
======================================================================

→ For 5-6 variables: Both algorithms acceptable (<10ms each)
→ For 7 variables: Prefer BoolMinGeo (~15× faster, ~3ms vs ~40ms)
→ For 8+ variables: Strongly recommend BoolMinGeo
  (98× faster at 8-var, projected 200+× faster at 9-var)
→ For embedded/real-time systems: BoolMinGeo essential for 7+ vars
